(54) **Process of and apparatus for forming thin films of metallic compounds**

(57) A process of forming films of metallic compounds on a substrate is disclosed, which essentially comprises producing a sputtered ultra-thin film and transforming this film into one of a metallic compound such as a metal oxide by exposing it to a reactive gas plasma. This operation is repeated until the resulting film product gains a desired thickness. An apparatus for car-

rying the process into practice is also disclosed, which comprises a sputtering electrode in a film-forming zone for producing a sputtered film of metal or metallic compound and a plasma generator in a plasma exposure zone to which the sputtered film is exposed to transform into one of a metallic compound. The two zones are respectively shielded against mutual interference.

EP 0 719 874 A1

Description

This invention relates to a process of and apparatus for forming thin films of metallic compounds by means of a sputtering technique.

Sputtering processes are widely known for the production of thin films of metals and metallic compounds such as metal oxides in which the targets of these materials are sputtered until their films are formed by deposition to a desired order of thickness. The rate of deposition of metallic compounds is generally inferior by comparison to metals per se. The same is true even with a metal target if oxygen is used in a reactive sputtering atmosphere, resulting in the formation of a metallic oxide film, with a further drawback in that the rate of deposition decreases as the amount of oxygen increases.

Metallic compound films as produced by sputtering or vacuum deposition are often depleted of their constituent elements as in the case for example of a SiO_2 target which ends up with a film composition $\text{SiO}_x (x < 2)$. The depletion of oxygen in such a case may be countered by the addition of a mixture of argon (Ar) and oxygen (O_2) gases, but at the sacrifice of a reduction in the rate of film deposition by about one half to one-third.

The present inventors have previously proposed (as disclosed in Japanese Laid-Open Patent Publication No. 62-284076) a process in which an ultra-thin film is sputtered from a titanium or like metal onto a substrate and the resultant film is subjected to irradiation of an ion beam of oxygen or like reactive gas so as to transform into that of a titanium oxide or like metallic compound, these process steps being repeatedly carried out to achieve a desired film thickness. It has been later found, however, that the use of an ion bombarding gun involves a number of equipment components such as filaments, screen electrode, suppressor electrode and the like, not to speak of the necessity of replacing worn filaments, accompanied by pollution of a vacuum chamber, increased power requirement, undue temperature rise due to the use of neutralizers and other associated problems.

Japanese Laid-Open Patent Publication No. 4-4967 discloses a similar process and apparatus in which a sputtering electrode is combined with an ion gun. This prior system has a drawback in that the ion source is susceptible to the influence of arcing at the side of the sputter source as both sources are electrically coupled, and further in that a plurality of high vacuum pumps are required, leading to upsized and complicated equipment layout.

With the foregoing drawbacks of the prior art in view, the present invention seeks to provide an improved process of and apparatus for forming ultra-thin films of metallic compounds at high rate of yields and with stable quality.

More specifically, the invention provides a process of forming films of metallic compounds which comprises a first step of sputtering a metal or a metallic compound

target to form an ultra-thin film over a substrate and a second step of transforming said ultra-thin film of metal into that of a metallic compound by exposure to plasma of a reactive gas, said first and second steps being alternated repeatedly until the resultant film is finished to a desired thickness.

The process of the invention is carried into practice by an apparatus for forming films of metallic compounds which comprises a vacuum tank, a substrate holder rotatably mounted therein, a sputtering electrode means carrying a metal or metallic compound target thereon and defining a film-forming zone for forming a sputtered ultra-thin film over a substrate and a plasma generating means generating a reactive gas plasma and defining a plasma exposure zone to which said sputtered ultra-thin film is exposed.

Figure 1 is a partially cross-sectional plan view schematically illustrating an apparatus employed to carry the process of the invention into practice.

Figure 2 is a cross-sectional view taken along the lines I, II and III of Figure 1.

The term "ultra-thin film" as used herein denotes a significantly thin individual film or lamina (for example of the order of 1-6 angstroms) formed during each cycle of the inventive process in contrast to or as distinct from a final product film resulting from superimposition of such individual films.

The term "reactive gas" as used herein includes an oxidative gas such as oxygen, ozone and N_2O , a nitrate gas such as nitrogen and a carbonative gas such as acetylene.

Referring now to the drawings, there is shown a film-forming apparatus 10 embodying the invention. The apparatus 10 comprises a vacuum tank 11, a substantially cylindrical substrate holder 12 rotatably mounted in the vacuum tank 11, a pair of sputtering electrodes 13, 14 disposed in confronting relation to each other diametrically across the holder 12 and an inductive coupling type plasma generator or plasma source 15 including RF (high frequency) discharge chamber 16 in the form of a quartz tube having RF coils 17 wound thereon which are energized from a high frequency power source 18 through a matching box 19. Each of the sputtering electrodes 13, 14 defines at its inner surface a film-forming zone 13', (14') which is surrounded by a shielding member 20, (21) and which creates therein controlled sputtering atmosphere upon supply of a sputtering gas such as argon from a sputtering gas supply bottle 22, (23) through a massflow meter 24, (25). There are shown in Figure 1 two sputtering electrodes 13, 14 for purposes of illustration and in consideration of the case where two different target materials are used.

Target materials eligible for the purpose of the invention exemplarily include aluminum, titanium, zirconium, niobium, tin, chromium, tantalum, iron, silicon, tellurium, nickel-chrome and indium-tin alloys, of which silicon, titanium and zirconium are particularly preferred.

For purposes of illustration, silicon (Si) is used as a

target 26 attached on one sputtering electrode 13 and titanium (Ti) as a target 27 on the other sputtering electrode 14. Argon gas is introduced from the sputtering gas bottle 22, and the sputtering electrode 13 is energized with power from a power source 28 whereupon the silicon target 26 is sputtered to form an ultra-thin film of silicon upon a substrate (not shown) supported on the holder 12 rotating with power from a drive motor 29 (Figure 2). The Si film thus formed is then exposed to a plasma of oxygen gas introduced from a reactive gas supply bottle 32 through a massflow meter 33 and generated at a plasma exposure zone 30 defined in communication with the RF discharge chamber 16 and surrounded by a shielding member 31.

The reactive gas atmosphere at the plasma exposure zone 30 may be also controlled by establishing a magnetic field in close proximity to the plasma source 15 thereby to vary and regulate the plasma density.

Upon exposure to the oxygen gas plasma, the Si sputtered ultra-thin film on the substrate is oxidized and transformed into a film of SiO_2 . With the substrate holder 12 held in rotation, the cycle of alternate sputtering and plasma exposure modes of operation is repeated as many times as is required to achieve a desired cumulative thickness of the final product film. The process of the invention is also directed to the sputtering of a silicon oxide (SiO_2) film, in which instance the flow of oxygen gas from the supply bottle 32 can be regulated via mass-flow meter 33 to replenish its level in the RF discharge chamber 16 to make up for the loss or depletion of oxygen ($\text{SiO}_x < 2$) incurred during sputtering thereby ensuring stable SiO_2 film formation.

The other sputtering electrode 14 carrying a zirconium (Zr) target 27 is energized with power from a power source 34 to effect the formation of a Zr sputtered ultra-thin film on the substrate, followed by exposure of the film to a reactive gas plasma. The cycle of this operation is repeated in a manner similar to the SiO_2 film formation already described. The target material on the electrode 14 may be other metals or oxides thereof such as titanium or titanium oxide.

The above sputtering and plasma exposure operation on selected target materials is repeatedly carried out until there is produced a film laminate of SiO_2 , TiO_2 or ZrO_2 on the substrate which is anti reflection.

The film-forming apparatus 10 according to the invention is advantageous in that the film-forming zone 13', (14') at the sputtering electrode, 13, (14) shielded as at 20, (21) against intrusion of the reactive or oxygen gas from the oxygen supply bottle 32 which would otherwise adversely affect the rate of sputtering, and the plasma exposure zone 30 at the RF discharge chamber 16 is likewise shielded as at 31 against entry of the sputtering gas from the sputtering gas supply bottle 22, (23), the respective gases being separately withdrawn via vacuum pump 35 (Figure 2). The arrangement is effective particularly where a plurality of sputtering targets are provided in close vicinity. The inventive apparatus 10 is

further advantageous in that the sputtering discharge and the reactive gas inductive coupling discharge are independently controllable without mutual interference to ensure stability of discharge and freedom from accidents and also in that the RF coils 17 at the plasma source 15 are disposed externally of the system so as to prevent possible pollution of the vacuum tank 11. The apparatus 10 contrary to the Kaufmann iron gun system, can dispense with the necessity of filaments, screen electrodes, suppressor electrodes, neutralizers and other equipment components and hence can be built relatively simple and compact.

The above film-forming operation according to the invention was conducted under the following conditions:

(1) Target: Silicon (Si)

Feed Power: 3.6 kw
Substrate Temperature: room temperature
Substrate Holder Drive: 100 r.p.m.
Shielded zone Pressure: 2.0×10^{-3} Torr
Ultra-thin Film Thickness: 2 - 6 angstroms

(2) Target: Zirconium (Zr)

Feed Power: 1.9 kw
Substrate Temperature: room temperature
Substrate Holder Drive: 100 r.p.m.
Shielded Zone Pressure: 5.0×10^{-3} Torr
Ultra-thin Film Thickness: 1 - 4 angstroms

(3) Reactive Gas Plasma: Oxygen (O_2)

Feed Power: 1 kw
Pressure: 1.4×10^{-3} Torr

Having thus described the invention, it will be obvious to those skilled in the art that changes or modifications may be made in the specific form and construction of the above film-forming apparatus without departing from the scope of the appended claims.

Claims

1. A process of forming films of metallic compounds which comprises a first step of sputtering a metal or a metallic compound target to form an ultra-thin film over a substrate and a second step of transforming said ultra-thin film of metal into that of a metallic compound by exposure to plasma of a reactive gas, said first and second steps being alternated repeatedly until the resultant film is finished to a desired thickness.
2. A process according to claim 1 characterized in that said target is selected from materials of the group consisting of aluminum, titanium, zirconium, ni-

bium, tin, chromium, tantalum, iron, silicon, tellurium, nickel-chrome and indium-tin.

3. A process according to claim 1 characterized in that said reactive gas is selected from the group consisting of oxygen, ozone, N_2O , nitrogen and acetylene. 5
4. A process according to claim 1 characterized in that said plasma is generated by an induction coupled plasma generator. 10
5. An apparatus for forming films of metallic compounds which comprises a vacuum tank, a substrate holder rotatably mounted therein, a sputtering electrode means carrying a metal or metallic compound target thereon and defining a film-forming zone for forming a sputtered ultra-thin film over a substrate and a plasma generating means generating a reactive gas plasma and defining a plasma exposure zone to which said sputtered ultra-thin film is exposed. 15 20
6. An apparatus according to claim 5 arranged to effect alternate sputtered film formation and exposure of the sputtered film to a reactive gas plasma in a repeated cycle of operation. 25
7. An apparatus according to claim 5 characterized in that said plasma generating means is an induction coupled plasma generator. 30
8. An apparatus according to claim 5 characterized in that said film-forming zone and said plasma exposure zone are respectively shielded against mutual interference. 35
9. An apparatus according to claim 5 characterized in that a pair of said sputtering electrode means are disposed in confronting relation to each other diametrically across said substrate holder. 40
